WEEK 6 PROGRESS REPORT

1. Introduction

Week 6 focused on workflow state management, persistent memory and agent interoperability. The objective was to improve the agent's ability to track support-request processing, retain relevant information between interactions and operate within defined boundaries.

2. Activities Undertaken

Activity	Work Undertaken	Outcome
Workflow state management	Implemented and reviewed a workflow state model covering IDLE, DRAFT_CREATED, AWAITING_APPROVAL, SUBMITTED and FAILED. The model records the student identifier, active support-request reference, last tool used, stop reason, number of turns and whether persistent memory was used.	Workflow state can be tracked and inspected during agent execution.
Agent workflow integration	Integrated workflow-state tracking with the LangGraph-based agent workflow. Tool results update the recorded state, allowing the application to track relevant events such as draft creation, submission and tool failure.	The agent workflow and state model work together to record execution progress.
Persistent memory	Implemented and reviewed a limited memory use case that retains an active support-request reference for retrieval during a later interaction. This enables continuity when a student returns to ask about an existing request.	The agent can use relevant stored information without needing to retain the entire conversation as persistent memory.
Memory access and data handling	Documented the purpose of persistent memory, the information retained, access restrictions, retention arrangements and deletion procedures. The design distinguishes temporary session state from information stored for later use.	Data-handling rules and memory-management responsibilities are documented.

MCP-style interface specification	Prepared and verified an interface specification describing support-request and memory-related capabilities, their expected inputs and outputs, and relevant security boundaries.	The project has a documented MCP-style interface specification. This is a specification of the interface, rather than a claim that a separate MCP server has been deployed.

3. Results Achieved

The Week 6 activities resulted in a workflow-state model integrated with the CampusConnect agent. The model provides a structured record of the agent's execution phase and relevant details, making it easier to inspect the progress of a support request and understand why an operation stopped or failed.

Persistent memory was implemented for a specific purpose: retaining an active support-request reference so that it can be retrieved when needed in a later interaction. This approach supports continuity while keeping persistent storage limited to information relevant to the selected use case.

The work also established documented data-handling rules covering the purpose of stored information, access, retention and deletion. These rules clarify the distinction between temporary workflow or session information and persistent memory, helping make the design easier to explain and review.

In addition, the MCP-style interface specification describes the agent's capabilities through explicit tool interfaces, including their inputs, outputs and security considerations. The specification provides a basis for understanding how these capabilities could be exposed for interoperability without misrepresenting the current implementation.

4. Conclusion

Week 6 completed the planned work on workflow state management, persistent memory, data handling and MCP-style interface documentation for CampusConnect. The implementation provides structured tracking of support-request processing and a limited memory capability for retrieving an active request during a later interaction.
